CHRISTOPHERVASQUEZ.NET | THREEFOLDEIGHT.COM

Website Architecture and Publishing Guide

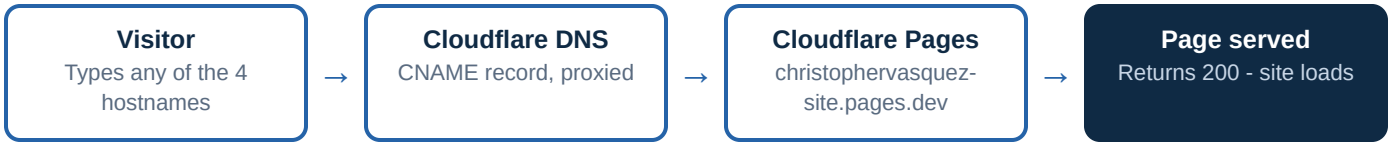

How your websites are built and hosted, and how to publish a new post yourself - from your phone or a computer, with no Muse automation involved.

> **The whole system in one sentence:** You edit files in a GitHub repository, and Cloudflare automatically builds and publishes the site every time you commit to the `main` branch.

WHEN YOU PUBLISH A POST

WHEN SOMEONE VISITS THE SITE

What this guide covers

- **Page 2** - Every component, what it does, and the full domain and DNS reference.
- **Page 3** - Where files live in the repository and how a publish actually happens.
- **Page 4** - Step-by-step directions: a text-only post, and a post with images.
- **Page 5** - A complete example post you can copy, editing an existing post, and what to do if a publish does not show up.

Current as of October 14, 2026. Both domains are registered at Porkbun. The older Wix site stays published as a rollback copy only - it is not part of the live setup described here.

Components - each part has one job

Component	Name / location	What it does
Domain registrar	Porkbun	Where both domains are registered and renewed: christophervasquez.net and threefoldeight.com.
Source files	GitHub repository `github.com/itsmecv/christophervasquez-site`	Holds every page, post, and image for the site. This is the only place you edit. The repository is public.
Build script	`build.py` in the repo	Turns the markdown posts and pages into the finished website. Cloudflare runs it for you - you never run it yourself.
Hosting / deploys	Cloudflare Pages project `christophervasquez-site`	Git-connected to the repository. Every push to `main` triggers a build and deploy, usually live in 1-2 minutes.
DNS	Cloudflare DNS	Points all four hostnames at the Pages project. See the table below.
Not in use	Old Pages project `christophervasquez`; Wix site	The old direct-upload Pages project still exists but serves nothing. Wix stays published as a rollback copy until you decide otherwise.

Domains and DNS - two domains, four hostnames

There are **two domains**. Each one is used with and without `www`, which gives four hostnames in total. All four are served by the same Pages project and show the same site.

Hostname	Record type	Points to	Proxied
christophervasquez.net	CNAME	christophervasquez-site.pages.dev	Yes
www.christophervasquez.net	CNAME	christophervasquez-site.pages.dev	Yes
threefoldeight.com	CNAME	christophervasquez-site.pages.dev	Yes
www.threefoldeight.com	CNAME	christophervasquez-site.pages.dev	Yes

> **There are no A records.** All four DNS records are CNAME records pointing at `christophervasquez-site.pages.dev`, proxied through Cloudflare. You do not need to change DNS to publish - it is already set up.

One exception: `social.threefoldeight.com` is separate. It still points at the Mastodon host and is not part of this website setup.

Order matters if domains are ever moved again

If the domains are ever moved to a different Cloudflare Pages project, point the DNS CNAME records at the new project's `pages.dev` address first, and only then attach the custom domains to the new project. Attaching the domains first leaves them stuck in a pending state.

Where files live in the repository

```
christophervasquez-site/
|
|-- build.py              The build script Cloudflare runs
|-- content/
|     |-- posts/          Every blog post lives here
|           |-- my-post-title.md
|           |-- another-post.md
|
|-- assets/               Every image lives here
      |-- my-post-0.jpg
      |-- my-post-1.jpg
```

- **Posts** are plain text files written in markdown, stored in `content/posts/`. One file equals one post.
- **Images** are stored in the `assets/` folder at the top level of the repository.
- **File names matter.** A post references its images by exact file name, so the name in the post must match the name in `assets/` character for character, including the ending (`.jpg` , `.png`).

How a publish happens, step by step

1. **You commit a change to `main`.** Adding a post, editing a page, and uploading an image are all commits.
2. **Cloudflare notices the push.** The Pages project `christophervasquez-site` is connected to the repository, so no one has to start the build manually.
3. **Cloudflare runs the build.** It runs `python3 build.py`, which converts the markdown files into finished web pages.
4. **Cloudflare deploys the result.** The new version replaces the old one at `christophervasquez-site.pages.dev`.
5. **All four hostnames serve the new version.** Because all four CNAME records point at that same address, christophervasquez.net and threefoldeight.com update together. The whole process usually takes 1-2 minutes.

> **That is the only automation on the site.** Cloudflare building and deploying on a push is built into the hosting. Writing posts, editing pages, and adding images are all manual steps you do in GitHub. Nothing else runs on its own, and Muse is not in the loop.

What a post file is made of

Every post has two parts. The top part, between the two `---` lines, is called frontmatter - it holds the title and the date. Everything below it is the post itself, written in markdown.

```
---
title: My Post Title
date: 2026-10-14
---

Your text starts here.
```

Dates use the format YYYY-MM-DD. Use the date you want shown on the post.

Directions - publish a text-only post

You can do this in the GitHub app on your phone or at `github.com` in a browser. The steps are the same.

1. Open the repository `itsmecv/christophervasquez-site`.
2. Open the `content` folder, then the `posts` folder.
3. Choose **Add file**, then **Create new file**.
4. Name the file after the post, in lowercase with hyphens, ending in `.md` - for example `my-post-title.md`.
5. Type the frontmatter and your text (see the template on page 3).
6. Choose **Commit changes**. Make sure it commits directly to the `main` branch.
7. Wait 1-2 minutes, then open christophervasquez.net and check the post is there.

Directions - publish a post with embedded images

Images are uploaded first, then referenced from the post. Two uploads in total: the image file, then the post file.

1. **Upload each image.** In the repository, open the `assets` folder, choose **Add file**, then **Upload files**, and pick the image from your phone or computer.
2. **Use a clear file name** with no spaces - for example `my-post-0.jpg` and `my-post-1.jpg`. Commit the upload to `main`.
3. **Create the post** in `content/posts/`, following the steps above.
4. **Insert each image** in the text where you want it to appear, using this exact pattern:

```
![describe the image](../assets/my-post-0.jpg)
```

- The text inside the square brackets is a description of the image.
- `../assets/` means: go up one folder from `posts/`, then into `assets/`. Type it exactly as shown.
- The file name after it must match the uploaded image exactly.

> **Order matters:** upload the images before you commit the post. If the post goes live first, it will show broken image placeholders until the images are uploaded and the site rebuilds.

Complete example - a post with two images

Copy this structure and replace the title, date, text, and image names with your own. The two image files - `example-post-0.jpg` and `example-post-1.jpg` - would be uploaded to `assets/` first, and this text would be saved as `example-post.md` in `content/posts/`.

```
---
title: Example Post With Images
date: 2026-10-14
---

Lorem ipsum dolor sit amet, consectetur adipiscing elit.
Sed do eiusmod tempor incididunt ut labore et dolore
magna aliqua. Ut enim ad minim veniam.

![a photo of something](../assets/example-post-0.jpg)

## A Subheading

Duis aute irure dolor in reprehenderit in voluptate
velit esse cillum dolore eu fugiat nulla pariatur.

![another image](../assets/example-post-1.jpg)

Sed ut perspiciatis unde omnis iste natus error sit
voluptatem accusantium doloremque laudantium.
```

Edit an existing post or page

1. Open the repository and find the file - posts are in `content/posts/`.
2. Open the file and choose the pencil / **Edit** option.
3. Make your changes, then choose **Commit changes** to `main`.
4. Wait 1-2 minutes and refresh the page on the live site to see the change.

If a publish does not show up

- **Wait, then refresh.** Give it a full 2 minutes, then reload the page. On a phone, close and reopen the tab if the old version still shows.
- **Check the commit went to `main`.** Only commits to `main` trigger a deploy. A commit on another branch does nothing to the live site.
- **Check the file name and location.** Posts must be in `content/posts/` and end in `.md`. Images must be in `assets/`.
- **For a missing image:** compare the name in the post with the name in `assets/`. One different character breaks the link.
- **Check the deploy in Cloudflare.** Open the Cloudflare dashboard, then the `christophervasquez-site` Pages project, to see whether the latest build succeeded or failed.

Quick reference: Repository - github.com/itsmecv/christophervasquez-site | Pages project - christophervasquez-site | Live address - christophervasquez-site.pages.dev | Build command - python3 build.py | Registrar - Porkbun
